CSE 431 Computer Architecture Fall 2015

Chapter 5C: Exploiting the Memory Hierarchy: TLBs

Mary Jane Irwin (www.cse.psu.edu/~mji)

[Adapted from Computer Organization and Design, 5th Edition, Patterson & Hennessy, © 2014, MK]

CSE431 Chapter 5C.1

Irwin, PSU, 2015

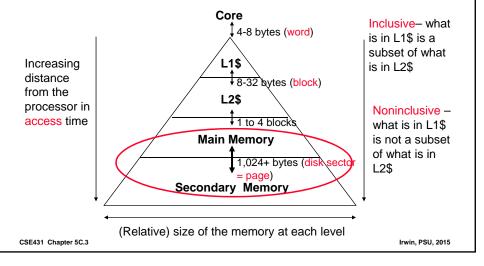

Reminders

- This week
 - Virtual memory hardware support (TLBs) P&H, 5.6-5.8
 - VLIW datapaths P&H 4.10
- Next week
 - Exam 1, Tuesday, October 6th, 20:15 to 22:15, Location 22 Deike
 - Static SuperScalar (SS) datapaths P&H 4.10 and 6.4 (and my slides)
- Reminders
 - HW3 dropbox closes midnight Oct 1st
 - Quiz 3 dropbox closes midnight Oct 4th
 - Second evening exam scheduled
 - Tuesday, November 17th, 20:15 to 22:15, Location 22 Deike
 - Please let me know ASAP if you have a conflict !!

CSE431 Chapter 5C.2 Irwin, PSU, 2015

Review: The Memory Hierarchy

□ Take advantage of the principle of locality to present the user with as much memory as is available in the cheapest technology at the speed offered by the fastest technology

How is the Hierarchy Managed?

- □ registers ↔ memory
 - by compiler (programmer?)
- □ registers ↔ cache ↔ main memory
 - by the cache controller hardware
 - by the memory controller hardware
- □ main memory ↔ secondary memory (flash, disk)
 - by the operating system (virtual memory)
 - virtual address to physical address mapping
 - assisted by the hardware (TLB, page tables)
 - by the programmer with OS support (files)

CSE431 Chapter 5C.4 Irwin, PSU, 2015

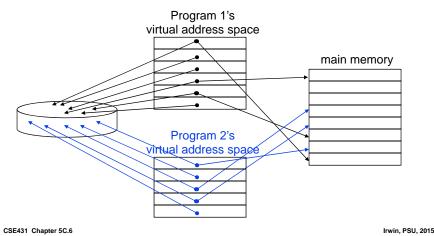

Virtual Memory Concepts

- □ Use main memory as a "cache" for secondary memory
 - Allows efficient and safe sharing of main memory among multiple processes/threads (running programs)
 - Each program is compiled into its own private virtual address space
 - Provides the ability to run programs and data sets larger than the size of physical memory
 - Simplifies loading a program for execution by providing for code relocation (i.e., the code/data can be loaded in main memory anywhere the OS can find space for it)
- The core and OS work together to translate virtual addresses to physical addresses
 - A virtual memory miss (i.e., when the page is not in physical memory) is called a page fault
- □ What makes it work efficiently? the Principle of Locality
 - Programs tend to access a only small portion of their address space over long portions of their execution time

CSE431 Chapter 5C.5 Irwin, PSU, 2015

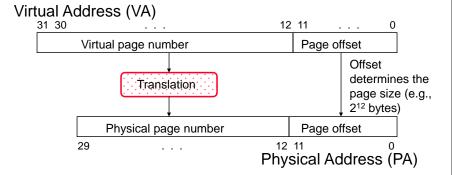

Two Programs Sharing Physical Memory

- □ A program's address space is divided into pages (all one fixed size) or segments (variable sizes)
 - The starting location of each page (either in main memory or in secondary memory) is contained in the program's page table

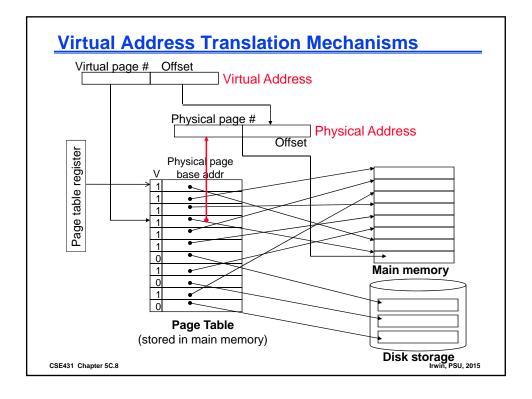

Address Translation

□ A virtual address is translated to a physical address by a combination of hardware and software

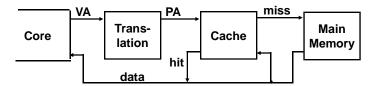

□ So each memory request first requires an address translation from the virtual space to the physical space

CSE431 Chapter 5C.7 Irwin, PSU, 2015

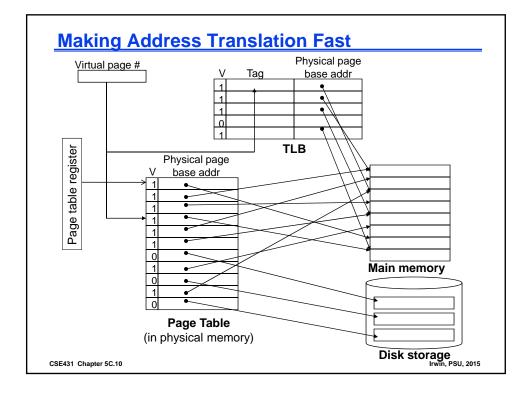

Virtual Addressing with a Cache

Thus it takes an extra memory access to translate a VA to a PA

- □ This makes memory (cache) accesses very expensive (if every access is really *two* accesses)
- □ The hardware fix is to use a Translation Lookaside Buffer (TLB) – a fast, small cache that keeps track of recently used address mappings to avoid having to do a page table lookup in memory (i.e., cache or main memory)

CSE431 Chapter 5C.9 Irwin, PSU, 2015

Translation Lookaside Buffers (TLBs)

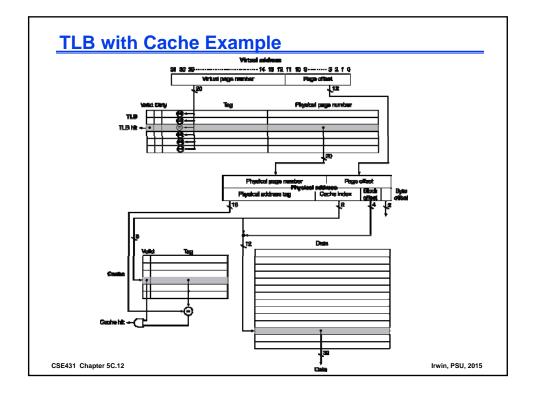

- Just like any other cache, the TLB can be organized as fully associative, set associative, or direct mapped
 - simplescalar defaults are itbl:16:4096:4:1 (16 sets per way, 4-way set associative so 64 entries, 4096B pages) and dtlb:32:4096:4:1 and tlb:lat 30 (cycles to service a TLB miss)

| V | Virtual Page # | Physical Page # | Dirty | Ref | Access |
|---|----------------|-----------------|-------|-----|--------|
| | | | | | |
| | | | | | |
| | | | | | |
| | | | | | |

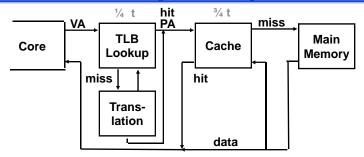

V = Valid?, Dirty = is the page dirty (so will have to be written back on replacement)?, Ref = Referenced recently?, Access = Write access allowed?

- □ TLB access time is typically much smaller than cache access time (because TLBs are much smaller than caches)
 - TLBs are typically not more than 512 entries even on high end machines

CSE431 Chapter 5C.11 Irwin, PSU, 2015

A TLB in the Memory Hierarchy

- A TLB miss is it a page fault or merely a TLB miss?
 - If the page is loaded into main memory, then the TLB miss can be handled (in hardware or software) by loading the translation information from the page table into the TLB
 - Takes 10's of cycles to find and load the translation info into the TLB
 - If the page is not in main memory, then it's a true page fault
 - Takes 1,000,000's of cycles to service a page fault
- □ TLB misses are much more frequent than true page faults

CSE431 Chapter 5C.13

Irwin, PSU, 2015

TLB Event Combinations

| TLB | Page Table | Cache | Possible? Under what circumstances? |
|------|---------------|-------|-------------------------------------|
| Hit | Hit | Hit | |
| Hit | Hit | Miss | |
| Miss | Hit | Hit | |
| Miss | Hit | Miss | |
| Miss | Miss | Miss | |
| Hit | Miss | Miss/ | |
| | | Hit | |
| Miss | Miss | Hit | |

CSE431 Chapter 5C.14

Irwin, PSU, 2015

Handling a TLB Miss

- Consider a TLB miss for a page that is present in memory (i.e., the Valid bit in the page table is set)
 - A TLB miss (or a page fault exception) must be asserted by the end of the same clock cycle that the memory access occurs so that the next clock cycle will begin exception processing

| Register | CP0 Reg# | Description | |
|----------|----------|------------------------------------|--|
| EPC | 14 | Where to restart after exception | |
| Cause | 13 | Cause of exception | |
| BadVAddr | 8 | Address that caused exception | |
| Index | 0 | Location in TLB to be read/written | |
| Random | 1 | Pseudorandom location in TLB | |
| EntryLo | 2 | Physical page address and flags | |
| EntryHi | 10 | Virtual page address | |
| Context | 4 | Page table address & page number | |

CSE431 Chapter 5C.16 Irwin, PSU, 2015

A MIPS Software TLB Miss Handler

■ When a TLB miss occurs, the hardware saves the address that caused the miss in BadVAddr and transfers control to 8000 0000_{hex}, the location of the TLB miss handler

TLBmiss:

- tlbwr copies from EntryLo into the TLB entry selected by the control register Random
- □ A TLB miss takes about a dozen clock cycles to handle

CSE431 Chapter 5C.17 Irwin, PSU, 2015

Some Virtual Memory Design Parameters

| | Paged VM | TLBs |
|-----------------------|-------------------------------|-----------------------|
| Total size (blocks) | 16,000 to 250,000 | 40 to 1,024 |
| Total size (KB) | 1,000,000 to 1,000,000,000 | 0.25 to 16 |
| Block size (B) | 4000 to 64,000 | 4 to 32 |
| Hit time | | 0.25 to 1 clock cycle |
| Miss penalty (clocks) | 10,000,000 to 100,000,000 | 10 to 1,000 |
| Miss rates | 0.00001% to 0.0001% | 0.01% to 1% |

CSE431 Chapter 5C.18 Irwin, PSU, 2015

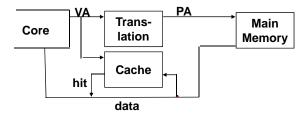

Current TLB Stats

| Characteristic | ARM Cortex-A8 | Intel Core i7 |
|------------------|---|--|
| Virtual address | 32 bits | 48 bits |
| Physical address | 32 bits | 44 bits |
| Page size | Variable: 4, 16, 64 KiB, 1, 16 MiB | Variable: 4 KiB, 2/4 MiB |
| TLB organization | 1 TLB for instructions and 1 TLB for data | 1 TLB for instructions and 1 TLB for data per core |
| | Both TLBs are fully associative, with 32 entries, round robin replacement | Both L1 TLBs are four-way set associative, LRU replacement |
| | TLB misses handled in hardware | L1 I-TLB has 128 entries for small pages, 7 per thread for large pages |
| | | L1 D-TLB has 64 entries for small pages, 32 for large pages |
| | | The L2 TLB is four-way set associative, LRU replacement |
| | | The L2 TLB has 512 entries |
| | | TLB misses handled in hardware |

CSE431 Chapter 5C.19 Irwin, PSU, 2015

Why Not a Virtually Addressed Cache?

 A virtually addressed cache would only require address translation on cache misses

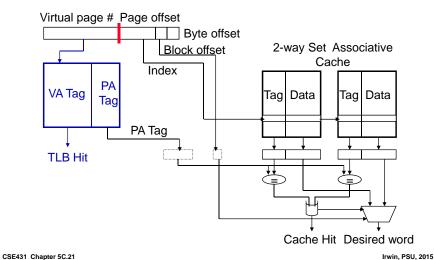

but

- Two programs which are sharing data will have two different virtual addresses for the same physical address – aliasing – so will have two copies of the shared data in the cache and two entries in the TBL which would lead to coherence issues
 - Must update all cache entries with the same physical address or the memory becomes inconsistent

CSE431 Chapter 5C.20 Irwin, PSU, 2015

Further Reducing Translation Time

- Can overlap the cache access with the TLB access
 - Works when the high order bits of the VA are used to access the TLB while the low order bits are used as index into cache

The Hardware/Software Interface

- What parts of the virtual to physical address translation is done by or assisted by the hardware?
 - Translation Lookaside Buffer (TLB) that caches the recent translations
 - TLB access time is part of the cache hit time
 - May need to allot an extra stage in the pipeline for TLB access
 - Page table storage, fault detection and updating
 - Page faults result in interrupts (precise) that are then handled by the OS
 - Hardware must support (i.e., update appropriately) Dirty and Reference bits (e.g., ~LRU) in the Page Tables
 - Disk placement
 - Bootstrap (e.g., out of disk sector 0) so the system can service a limited number of page faults before the OS is even loaded

CSE431 Chapter 5C.22 Irwin, PSU, 2015

Memory and OS Protection

- Different processes can share parts of their virtual address spaces
 - For example, run a program under control of a debugger, or sharing data and computing effort between processes
 - Need to protect against improper access
 - "improper" is defined by the programmer via system calls to the OS
 - Requires OS assistance via the page tables and locking mechanisms
- Hardware support for OS protection
 - Privileged supervisor mode (aka kernel mode)
 - Privileged instructions, registers and addresses
 - Page tables and other state information only accessible in supervisor mode
 - System call exception (e.g., syscall in MIPS)
 - etc., etc.

CSE431 Chapter 5C.23 Irwin, PSU, 2015

Common Memory Hierarchy Framework

CSE431 Chapter 5C.24

Irwin, PSU, 2015

Common Memory Framework

- The Principle of Locality:
 - Program likely to access a relatively small portion of the address space at any instant of time.
 - Temporal Locality: Locality in Time
 - Spatial Locality: Locality in Space
- Caches, TLBs, Virtual Memory all understood by examining how they deal with the four questions
 - 1. Where can an entry be placed in the upper level?
 - 2. How is an entry found if it is in the upper level?
 - 3. What entry is replaced on miss?
 - 4. How are writes handled?
- Page tables map virtual address to physical address
 - TLBs are important for fast translation

CSE431 Chapter 5C.25

Irwin, PSU, 2015

Q1&Q2: Where can a entry be placed/found?

| | # of sets | Entries per set |
|-------------------|-------------------------------|-----------------------------------|
| Direct mapped | # of entries | 1 |
| Set associative | (# of entries)/ associativity | Associativity (typically 2 to 16) |
| Fully associative | 1 | # of entries |

| | Location method | # of comparisons |
|-------------------|--|-------------------------|
| Direct mapped | Index | 1 |
| Set associative | Index the set; compare set's tags | Degree of associativity |
| Fully associative | Compare all entries' tags Separate lookup (page) table | # of entries |

CSE431 Chapter 5C.26 Irwin,

Q3: Which entry should be replaced on a miss?

- □ Easy for direct mapped only one choice
- □ Set associative or fully associative
 - Random
 - LRU (Least Recently Used)
- □ For a 2-way set associative, random replacement has a miss rate about 10% higher than LRU
- □ LRU is too costly to implement for high levels of associativity (> 16-way) since tracking the usage information is costly

CSE431 Chapter 5C.27 Irwin, PSU, 2015

Q4: What happens on a write?

- □ Write-through The information is written to the entry in the current memory level and to the entry in the next level of the memory hierarchy
 - Always combined with a write buffer so write waits to next level memory can be eliminated (as long as the write buffer doesn't fill)
- Write-back The information is written only to the entry in the current memory level. The modified entry is written to next level of memory only when it is replaced.
 - Need a dirty bit to keep track of whether the entry is clean or dirty
 - Virtual memory systems always use write-back of dirty pages to disk
- Pros and cons of each?
 - Write-through: read misses don't result in writes (so are simpler and cheaper), easier to implement
- Write-back: writes run at the speed of the cache; repeated writes require only one write to lower level

Irwin, PSU, 2015

Reminders

- Next lecture
 - VLIW datapaths P&H 4.10
- Next week
 - Exam 1, Tuesday, October 6th, 20:15 to 22:15, Location 22
 - Static SuperScalar (SS) datapaths P&H 4.10 and 6.4 (and my slides)
- Reminders
 - HW3 dropbox closes midnight Oct 1st
 - Quiz 3 dropbox closes midnight Oct 4th
 - Second evening exam scheduled
 - Tuesday, November 17th, 20:15 to 22:15, Location 22 Deike
 - Please let me know ASAP if you have a conflict !!

CSE431 Chapter 5C.29 Irwin, PSU, 2015
